

Cosmological Studies with SPICA/SAFARI after the Herschel Mission, in the JWST & ALMA Era

Alberto Franceschini
Universita' di PADOVA

SPICA/SAFARI Meeting Roma Feb 2013

The last of the series: the Herschel Observatory

1983: IRAS (Infrared Astronomical Satellite) is launched. It scans more than 100 times, providing an all-sky map at 100 and 1000 micrometers. It cataloged about 250,000 sources, detecting about 1000 new objects. IRAS discovered interstellar grains around stars, comets, and variations in brightness from interactions of warm dust clouds. It also revealed for the first time the central core of our galaxy, the Milky Way.

– +3 years warm

2003: The Spitzer Space Telescope was launched in August 2003. It is the last of NASA's "great observatories" in space. Spitzer is much more sensitive than prior infrared missions and will study the universe at a wide range of infrared wavelengths. Spitzer will concentrate on the study of brown dwarfs, super planets, protoplanetary and planetary debris disks, ultraluminous galaxies, active galaxies, and deep surveys of the early universe.

About 15000 Herschel sources in COSMOS and 10000 in Wide

IR & UV SFR estimates ...

From integrations
of 1500° LFs by:

Arnouts et al 2005
Schiminovic + 2005
Wyder + 2005
(@ low z)

Cucciatti + 2012
Shimasaku + 2005
(@ high z)

1. The bulk of SF activity at $z < 3-4$ appears to be produced by strongly dust-extinguished galaxies
2. UV bright objects instead dominate on average at $z > 4$

Evolutionary Population Properties of IR sources

Gruppioni + (in press)

Strong evidence for downsizing in the star formation history

Distribution of Dark Matter in the Millenium Simulation ...

125 Mpc/h

... plus physical (analytic) recipes to treat the baryon collapse & SF

Present models appear to largely underestimate the SFR density at high values of L_{IR} at large redshifts

...at the same time the best physical models appear to fit relatively well the galaxy stellar mass functions...

Menci et al. 2012

... but if you attempt to fit the luminosity functions, you dramatically overproduce the stellar mass function

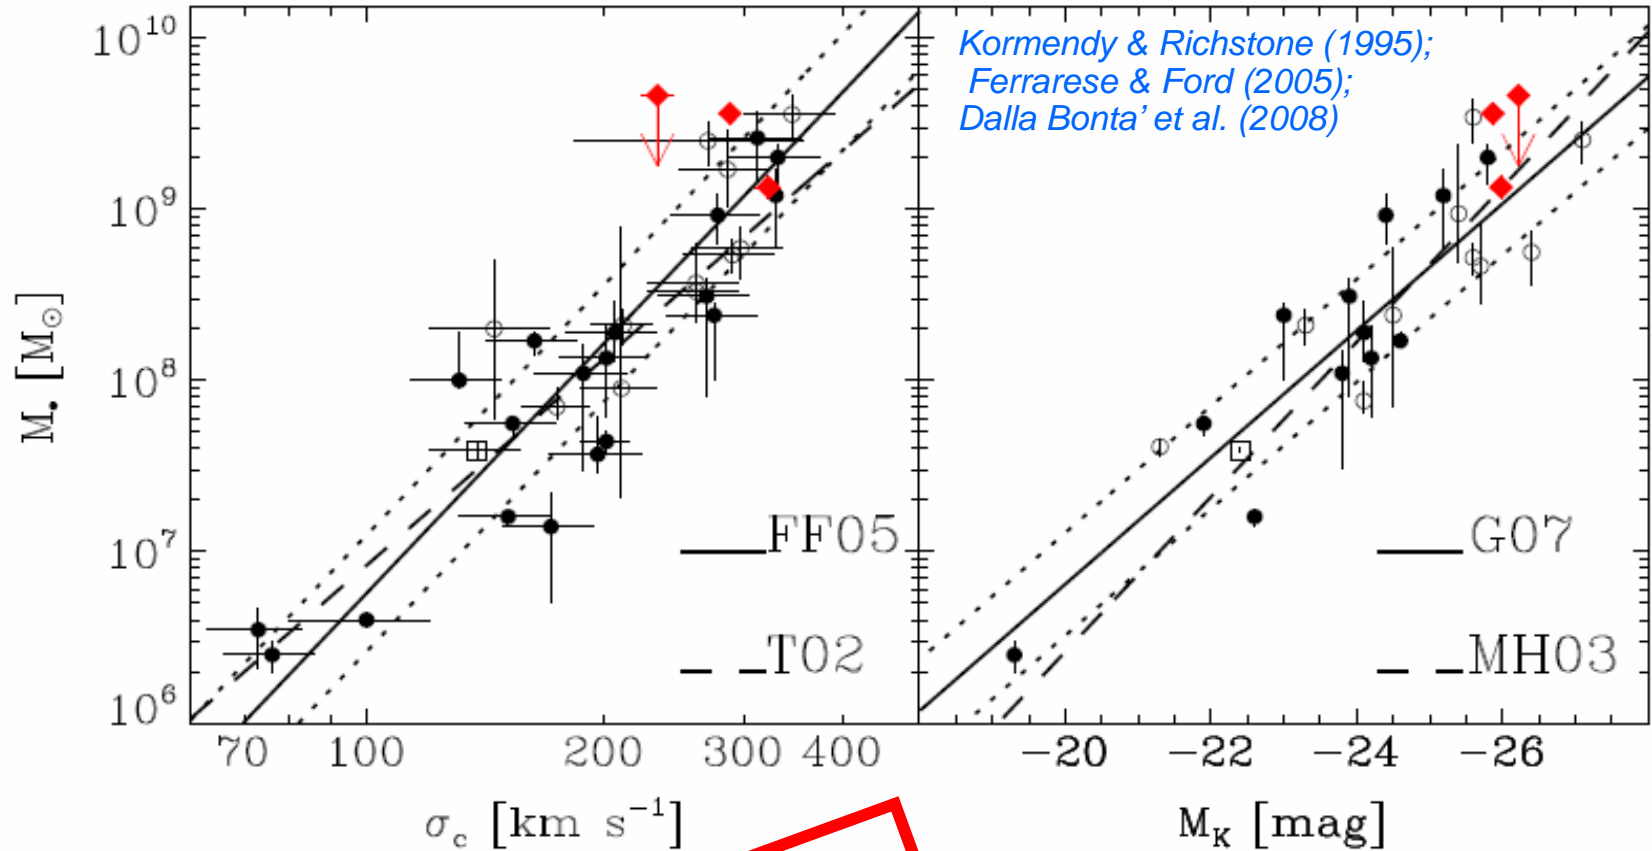

Supermassive Black Holes in the Nuclei of Galaxies & AGN activity

Most massive galaxies possess supermassive black holes in their nuclei.

The Nuclear BH / Host Bulge Relationship

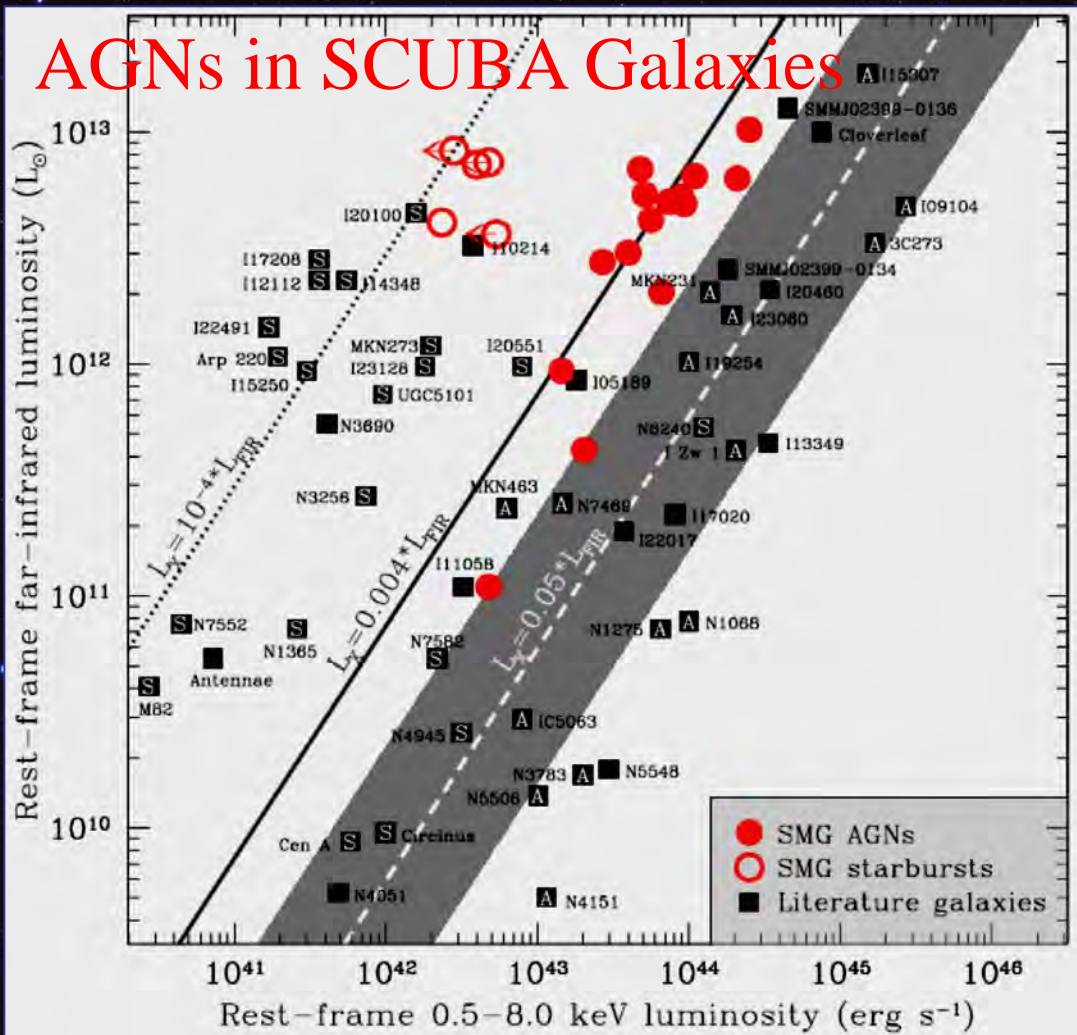

Question: where, when, and how the relation of SF and AGN has taken shape?

Left panel: Location of the SBHs masses of our BCG sample galaxies (diamonds) with respect to the $M_{\bullet}-\sigma_c$ relation by Ferrarese & Ford (2005). We plot the SBH masses based on resolved dynamical studies of ionized gas (open circles), water masers (open squares), and stars (filled circles) from Table 2 of Ferrarese & Ford (2005). The dashed line represents the Tremaine et al. (2002) relation. Right panel: Location of our BCG sample galaxies with respect to the near-infrared (K -band) $M_{\bullet}-L_{bulge}$ relation by Graham (2007). Data are taken from Table 2 of Graham (2007) and symbols are as in the left panel. Masses and magnitudes of NGC 5252, NGC 6251 and Cygnus A were adjusted to a distance obtained with $H_0 = 75 \text{ km s}^{-1} \text{ Mpc}^{-1}$. The dashed line represents the Marconi & Hunt (2003) relation. In both panels, we added the data relative to NGC 1399 (Houghton et al. 2006) and the dotted lines represent the 1σ scatter in M_{\bullet} .

AGN incidence in luminous sub-mm sources

AGNs in SCUBA Galaxies

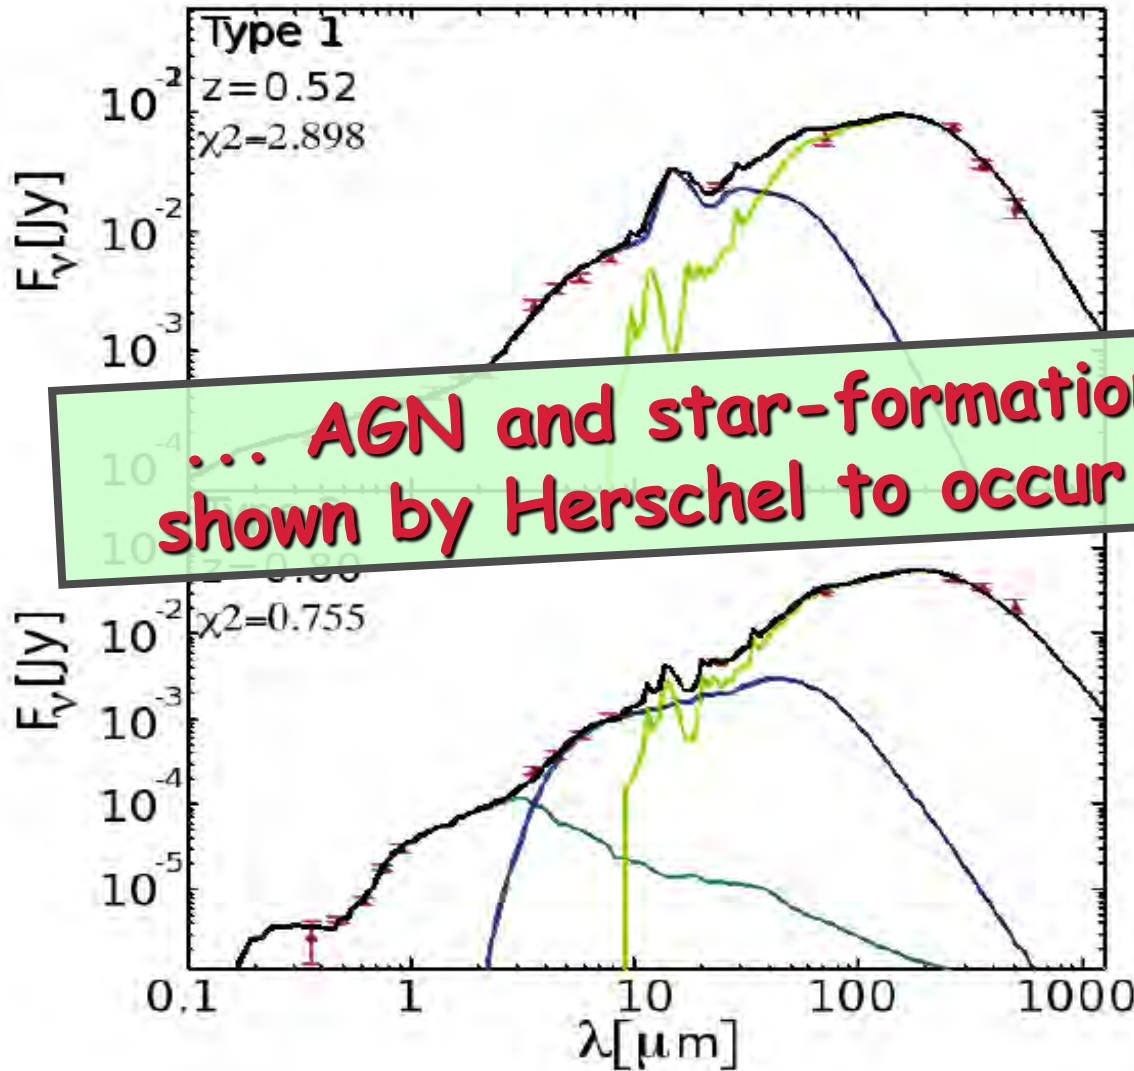

" As typical quasars are not undergoing intense star formation and already host massive black holes there must have been an earlier pre-quasar phase when these black holes grew. The likely signature of this earlier stage is simultaneous black-hole growth and star formation in distant luminous galaxies. We find that the black holes in these galaxies are growing almost continuously throughout periods of intense star formation. This activity appears to be more tightly associated with these galaxies than any other coeval populations. We show that the BH growth from these galaxies is consistent with that expected for the pre-quasar phase."

Alexander et al. 2005

Herschel Investigation of Quasi-Stellar Objects

... AGN and star-formation activities are shown by Herschel to occur simultaneously...

Example fits for a type 1 (upper panel) and a type 2 (lower panel) AGN. In red the data points; in blue the AGN/torus model; in light green the starburst component; in dark green the stellar component, and in black the total model SED. The reported χ^2 are reduced.

Hatziminoglou et al. 2010

After the Herschel mission ...

1. Consistent results from independent surveys, strong constraints on the high- z galaxy comoving emissivity and SFR
2. Current data show: strong positive evolution of the bolometric L + very strong negative evolution of the comoving density:
3. ... this quite at variance wrt *hierarchical clustering* predictions
4. Galaxy & AGN co-evolution, but very unclear any physical relationship between the two

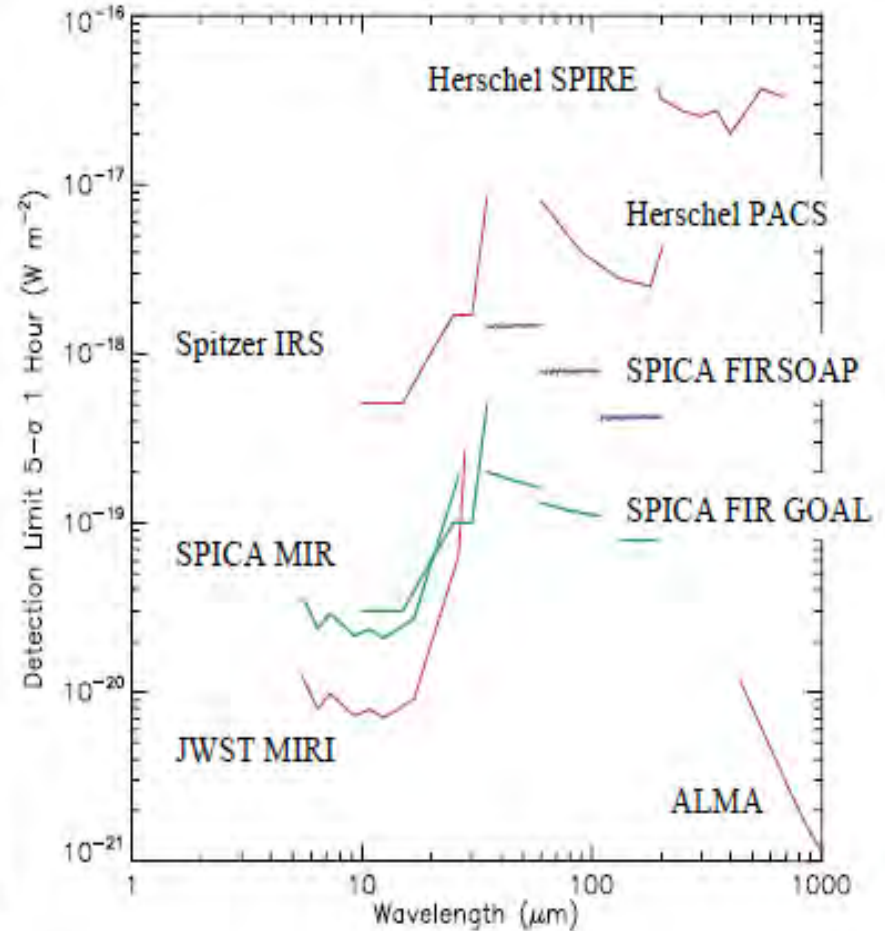

SPICA

Launch ~ 2018

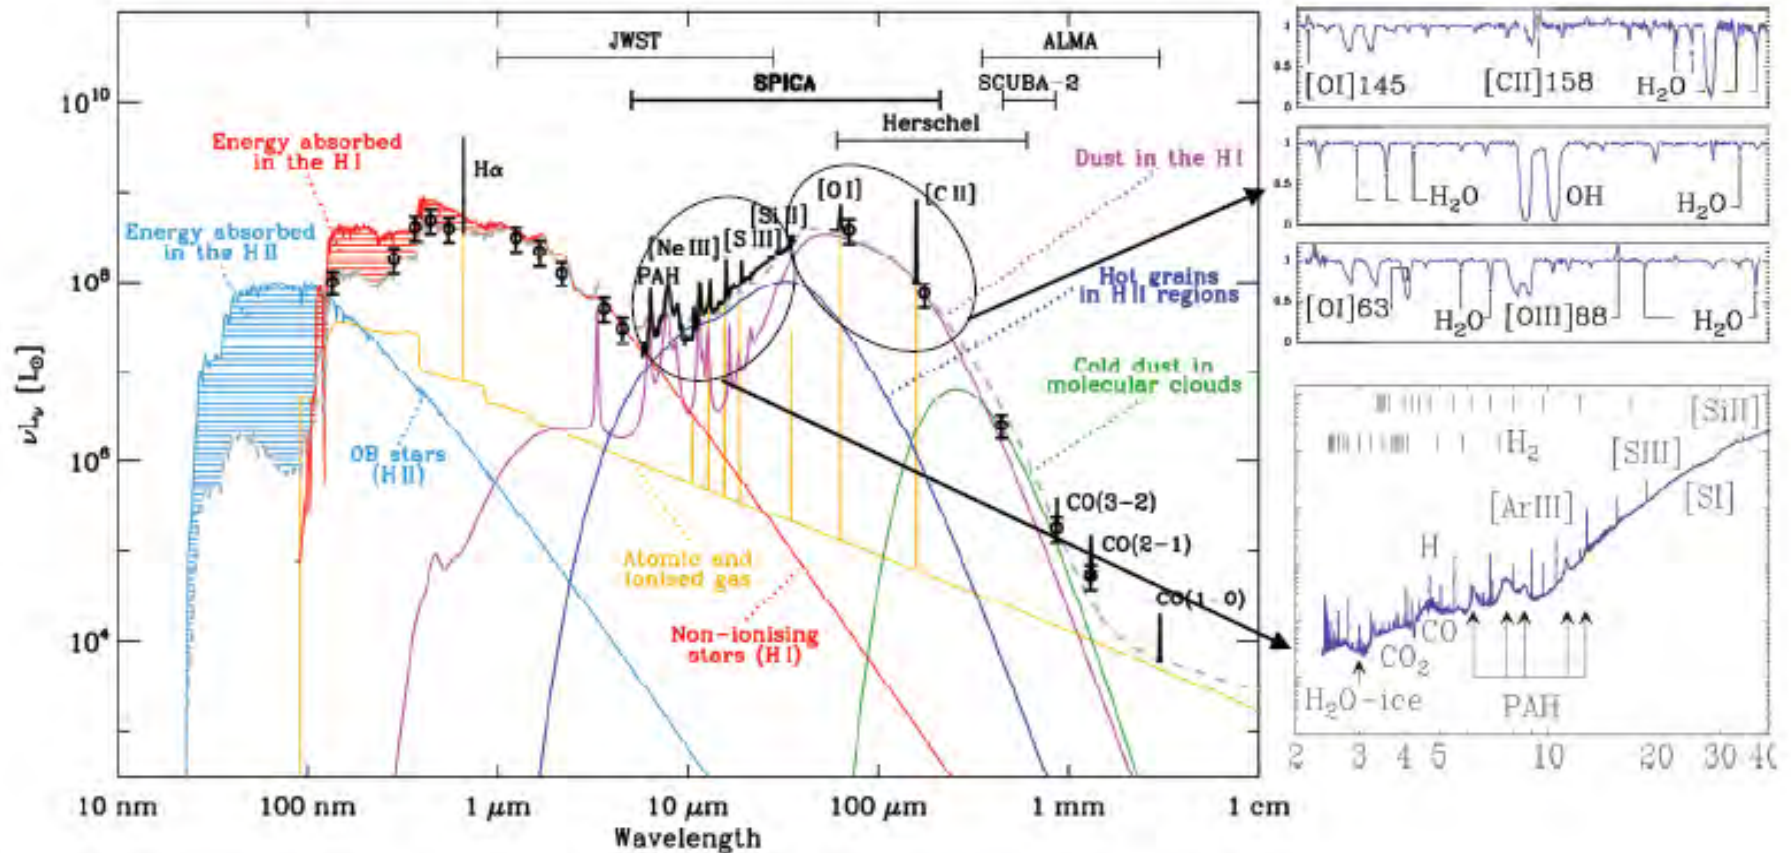

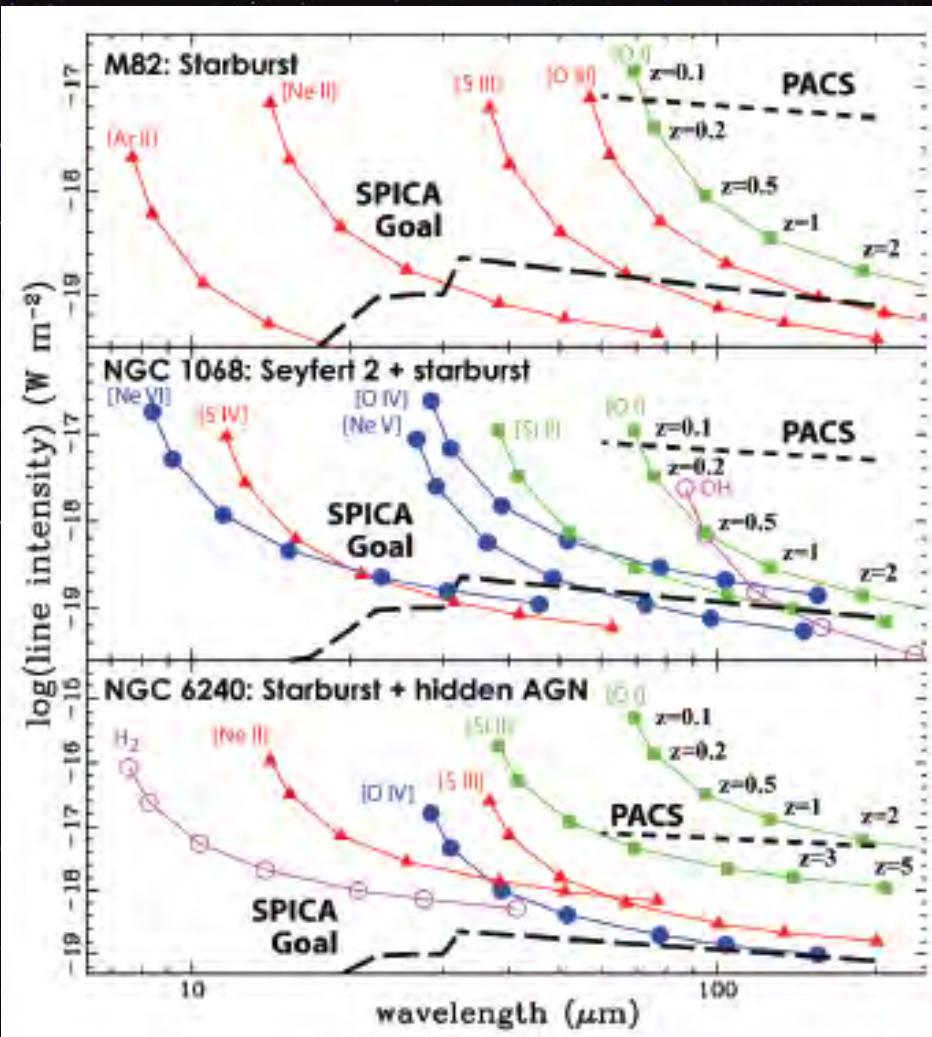

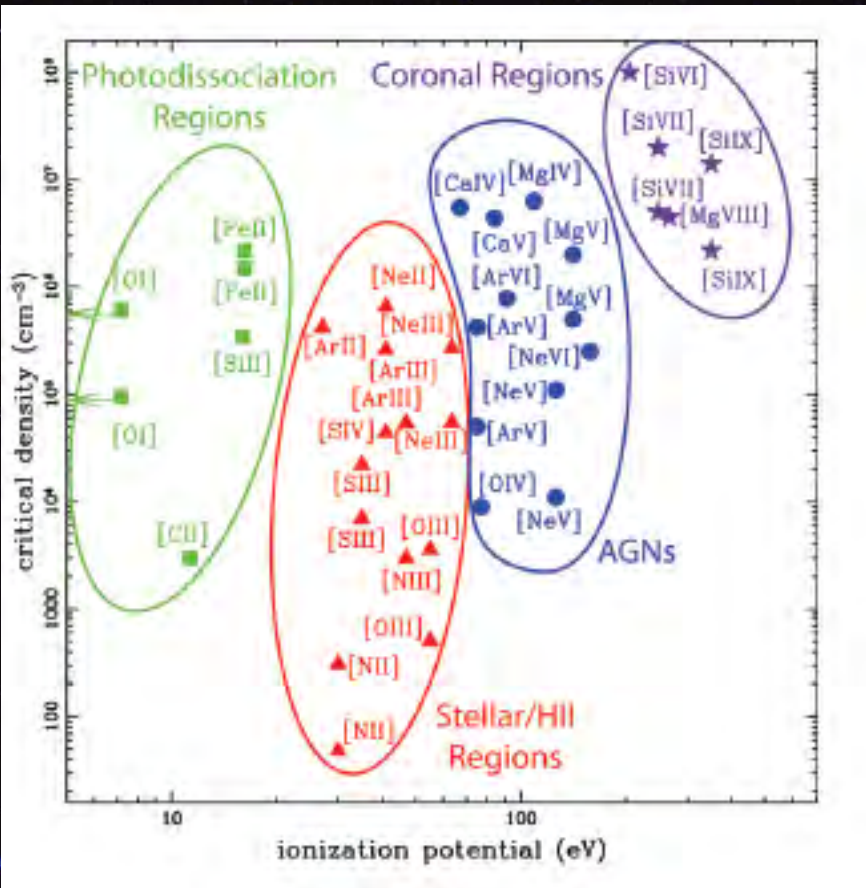

- 3.5-m telescope cooled to 4.5 K
- $\lambda = 5 - 200+ \mu\text{m}$

... thanks to the huge sensitivity gain offered by the cooled instrumentation

Given the extremely rich variety of ionic & molecular features in the spectral domain, a top priority case for the mission will be spectroscopy with high-spatial & spectral resolution of cosmic sources

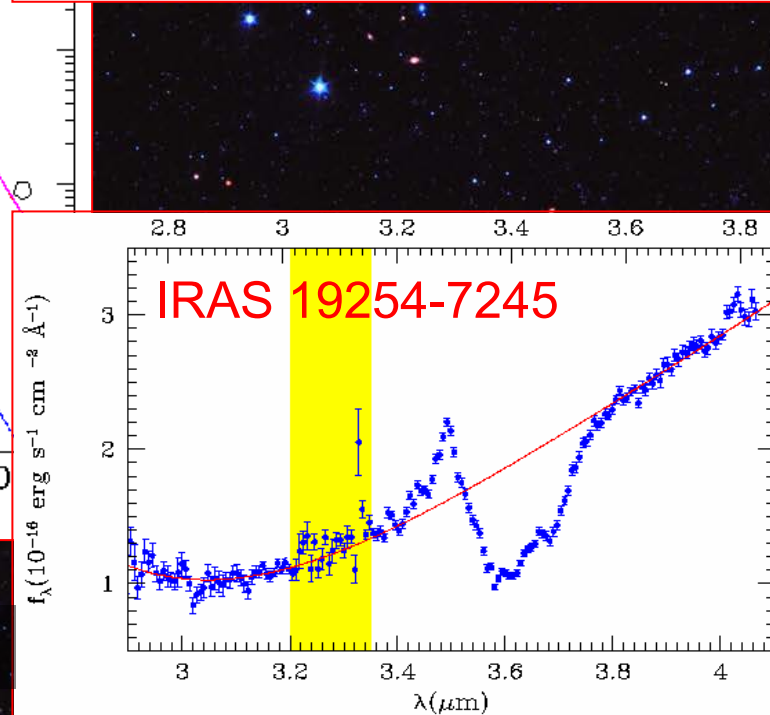

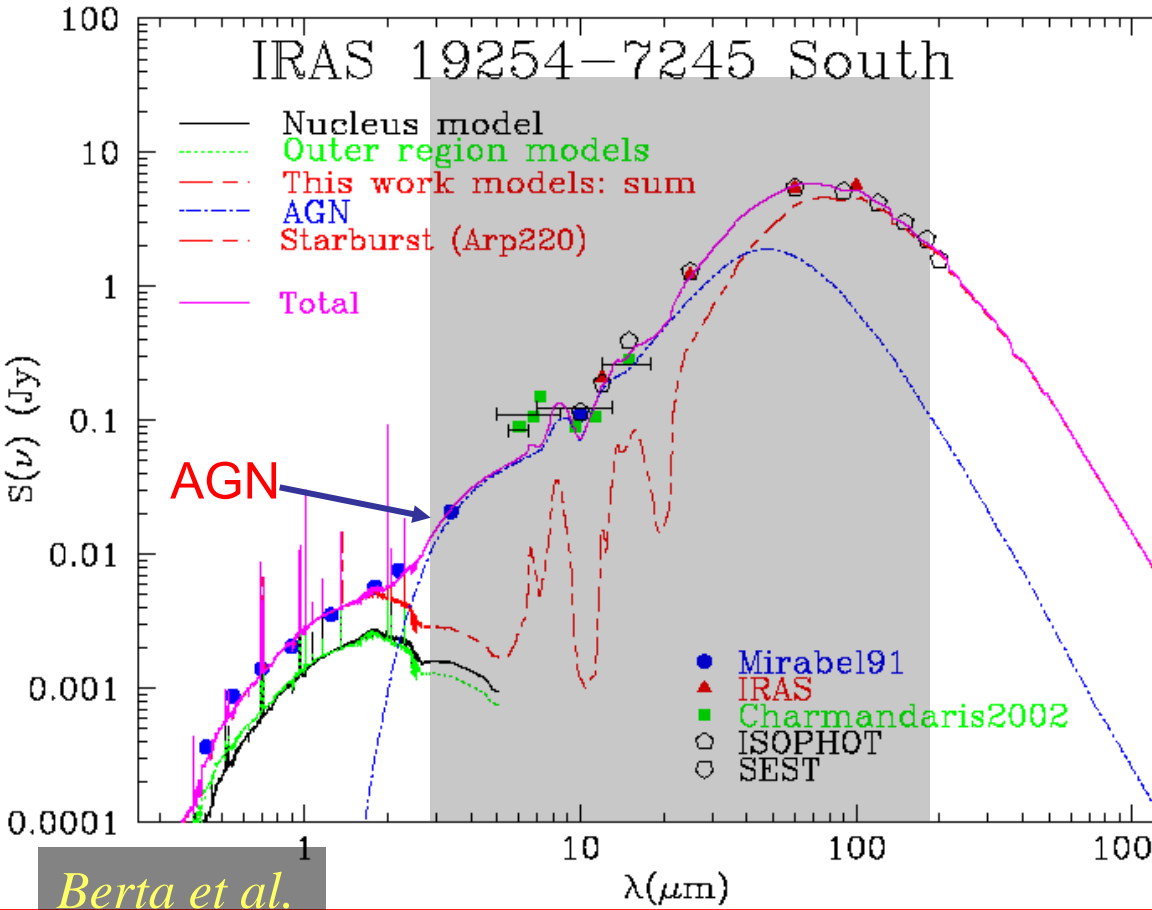

Key MIR/FIR emission lines visible with SPICA in three archetypical objects: M82 ($L_{\text{FIR}} \sim 4 \times 10^{10} L_{\odot}$), NGC1068 ($L_{\text{FIR}} \sim 2 \times 10^{11} L_{\odot}$) and NGC6240 ($L_{\text{FIR}} \sim 7 \times 10^{11} L_{\odot}$) - in each panel the upper/lower dashed lines denote the 5σ -1hr sensitivity of Herschel-PACS/SPICA respectively

IR diagnostics available for SPICA investigations

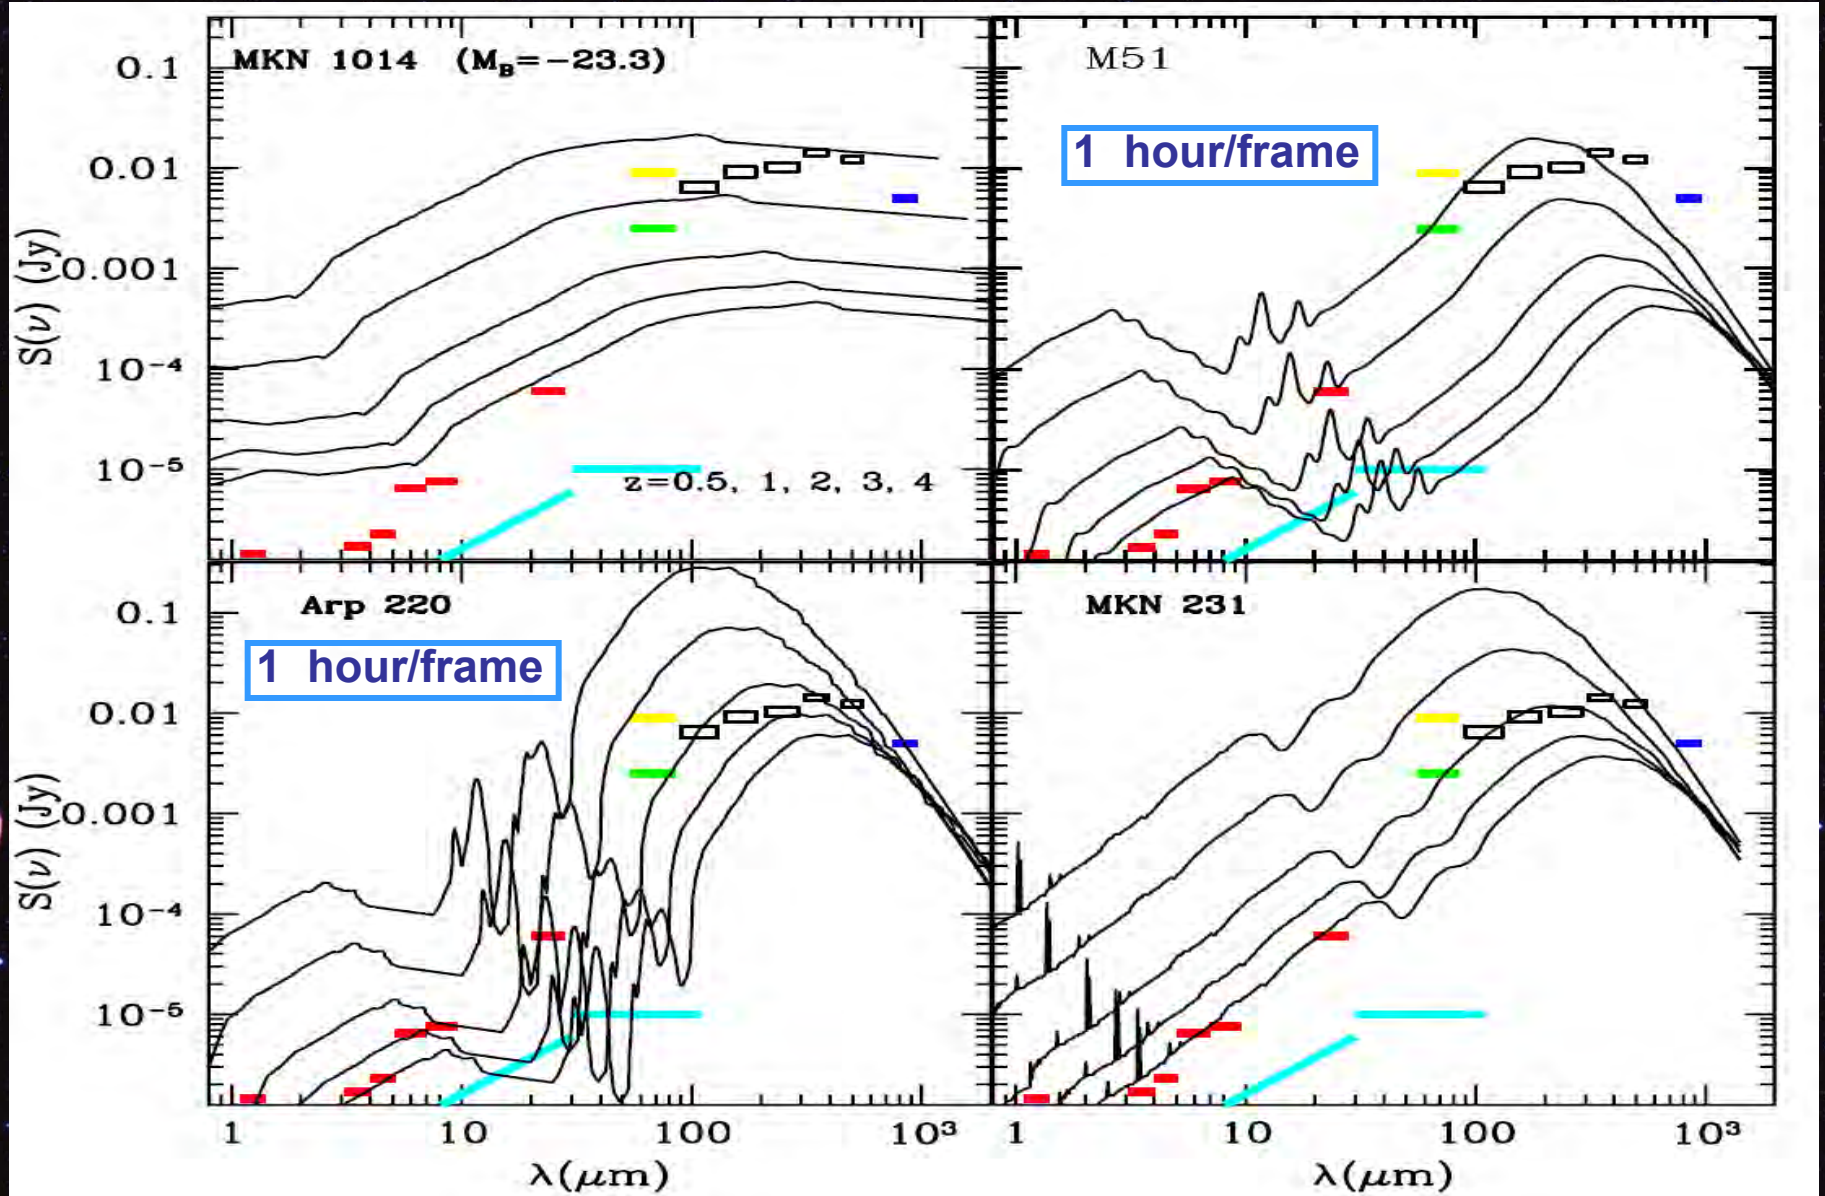

Lutz et al. 1998

VLT spec. (Risaliti et al)

- ★ Crucial steps forward will also be made by SPICA in the field of deep cosmological imaging surveys
- ★ Deep broad-band surveys => excellent sensitivity (still some limitation by spatial resolution at $\lambda > 100 \mu\text{m}$)
- ★ SPICA has a large *discovery space* if we consider that Herschel has essentially been blind at $\lambda < 100 \mu\text{m}$

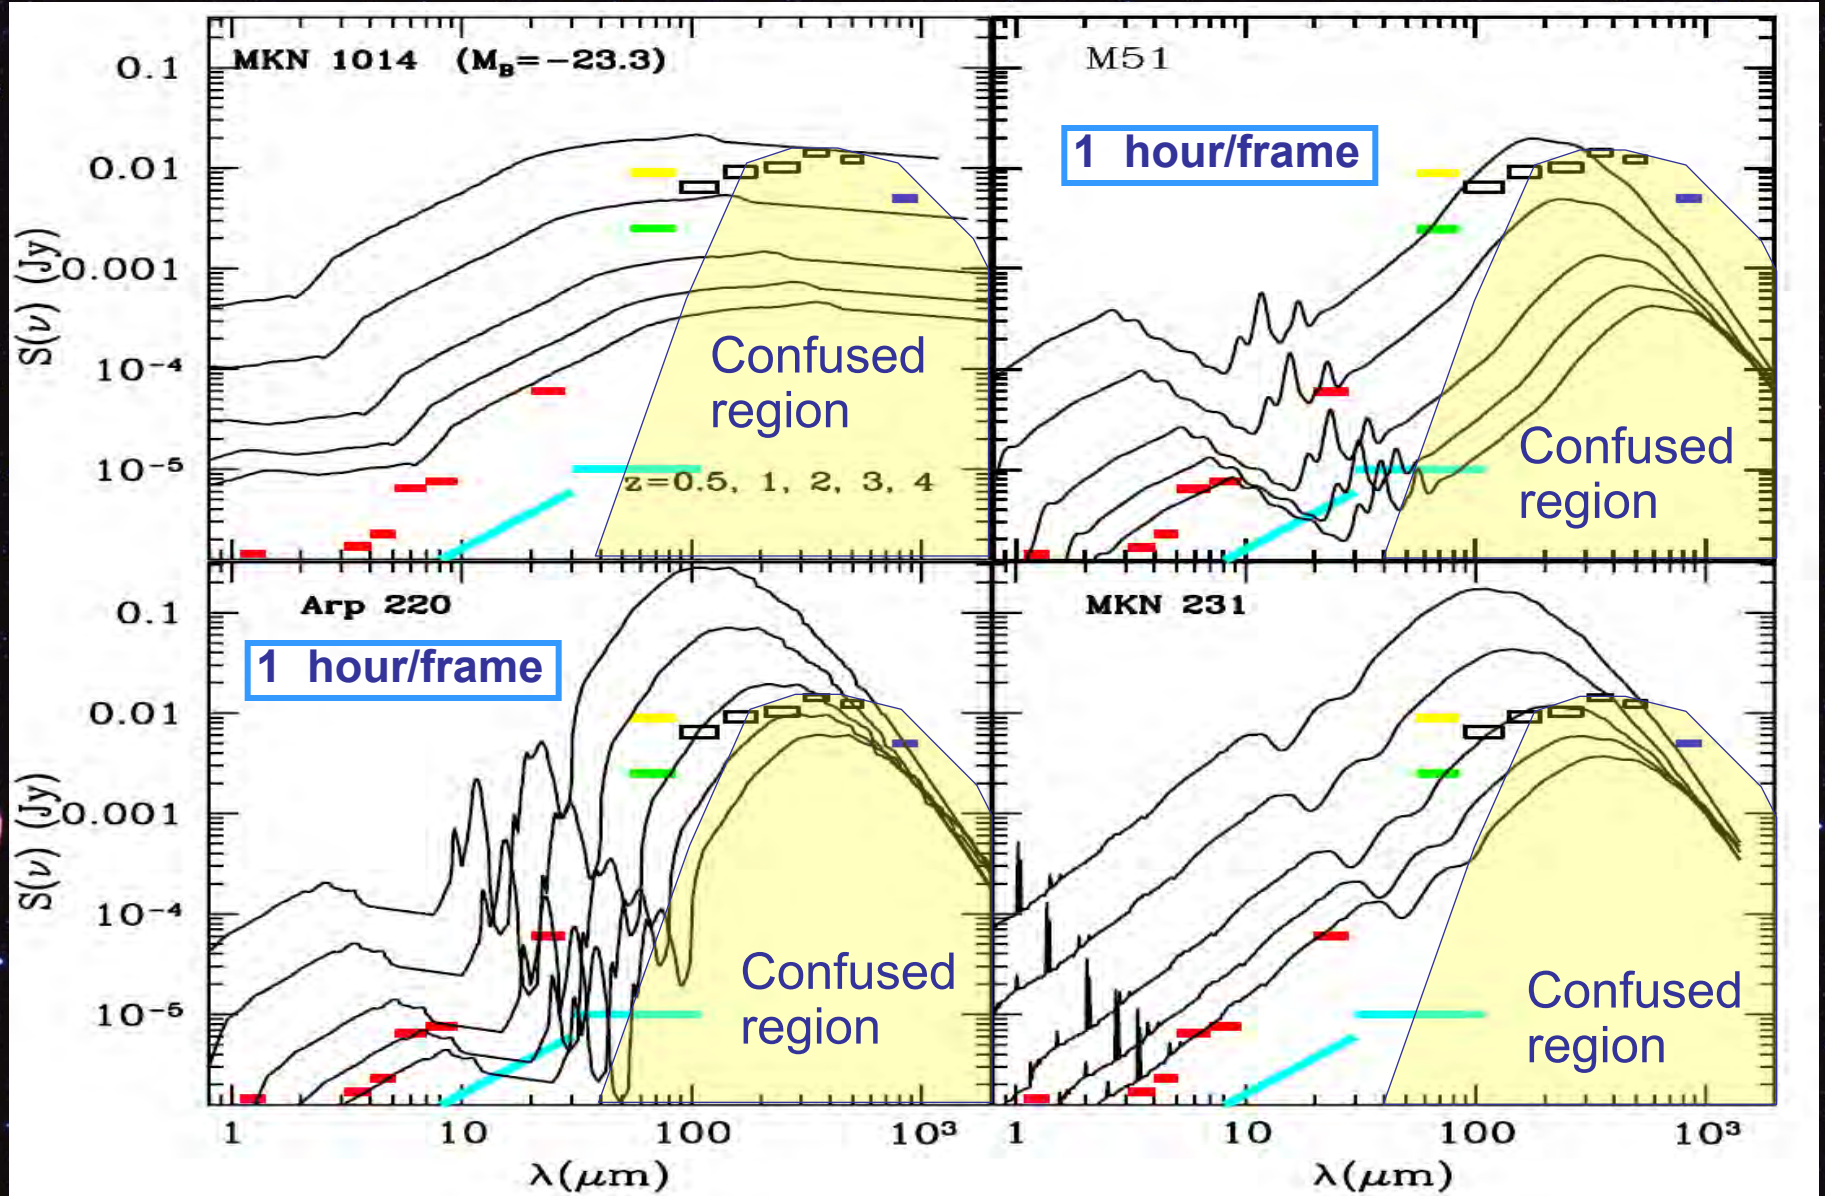

SPICA photometric mode sensitivity

SPICA's SOURCE CONFUSION vs. HSO's: a great improvement! ...

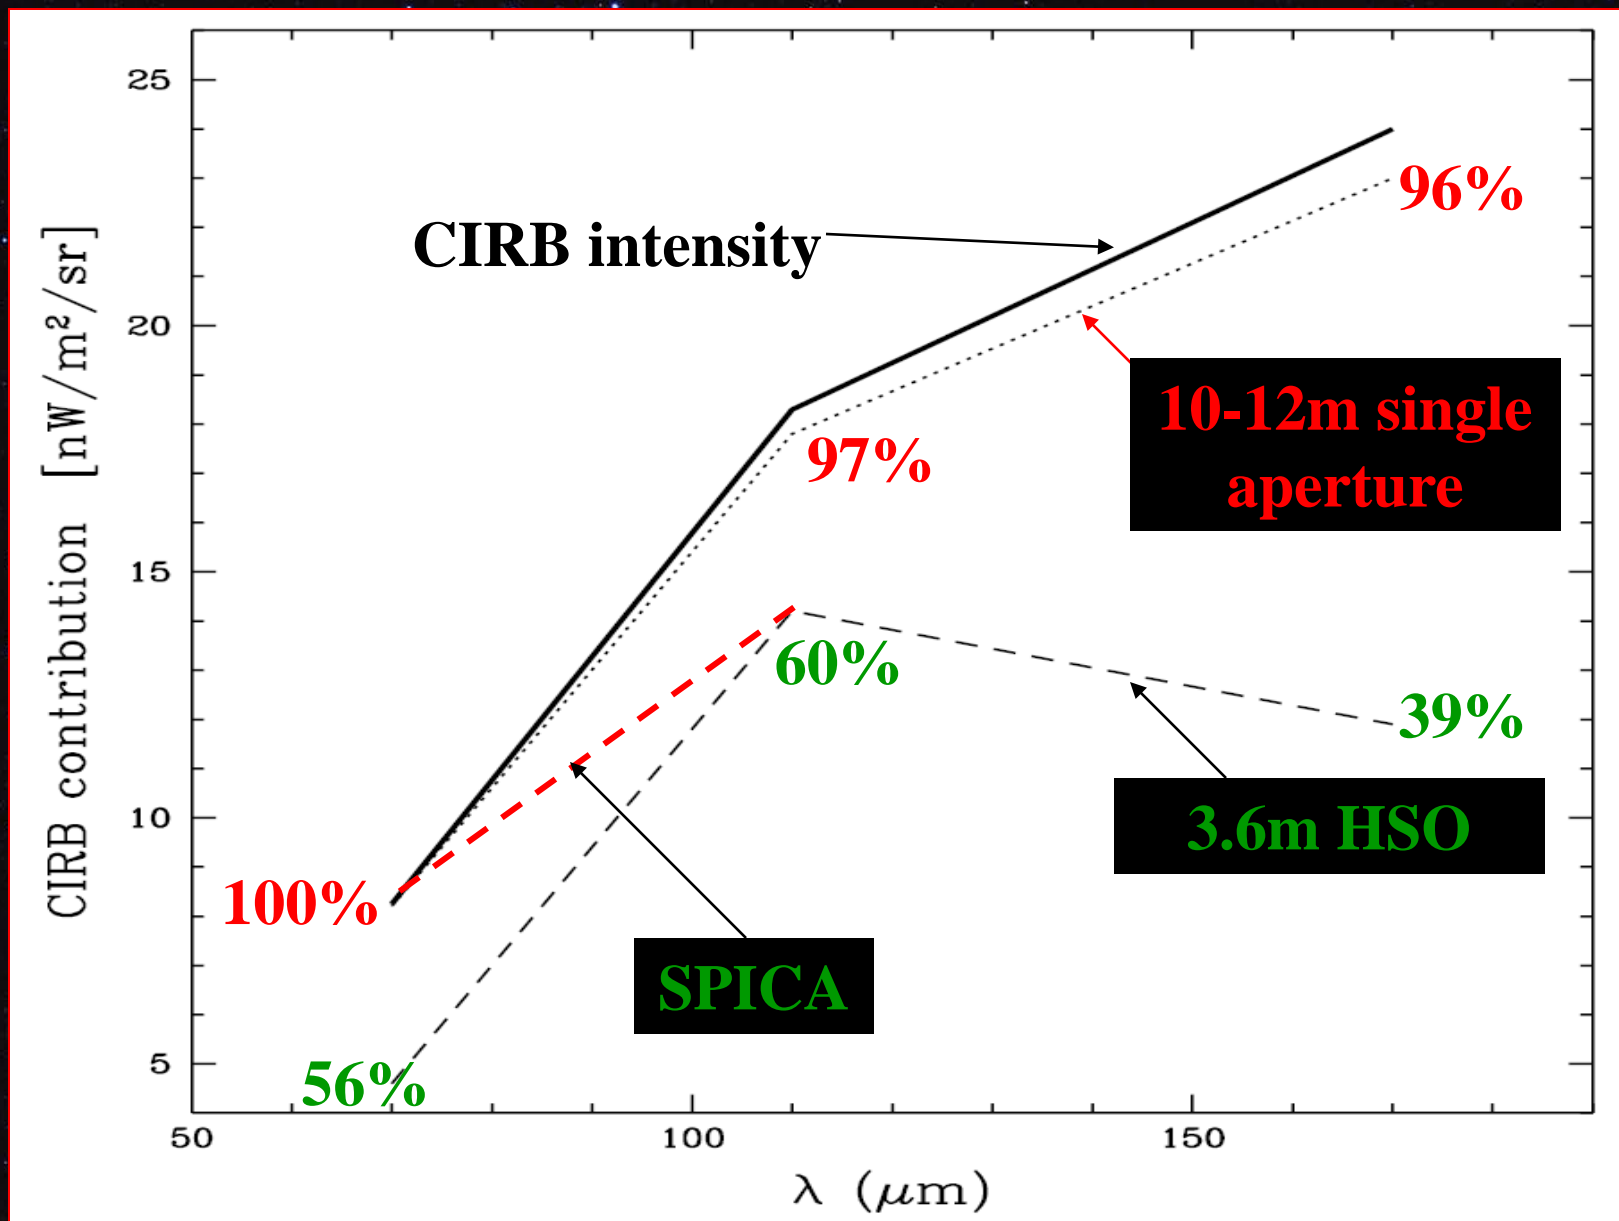

SPICA photometric mode sensitivity

"Resolvable fraction of the CIRB..."

"Resolvable fraction of the CIRB..."

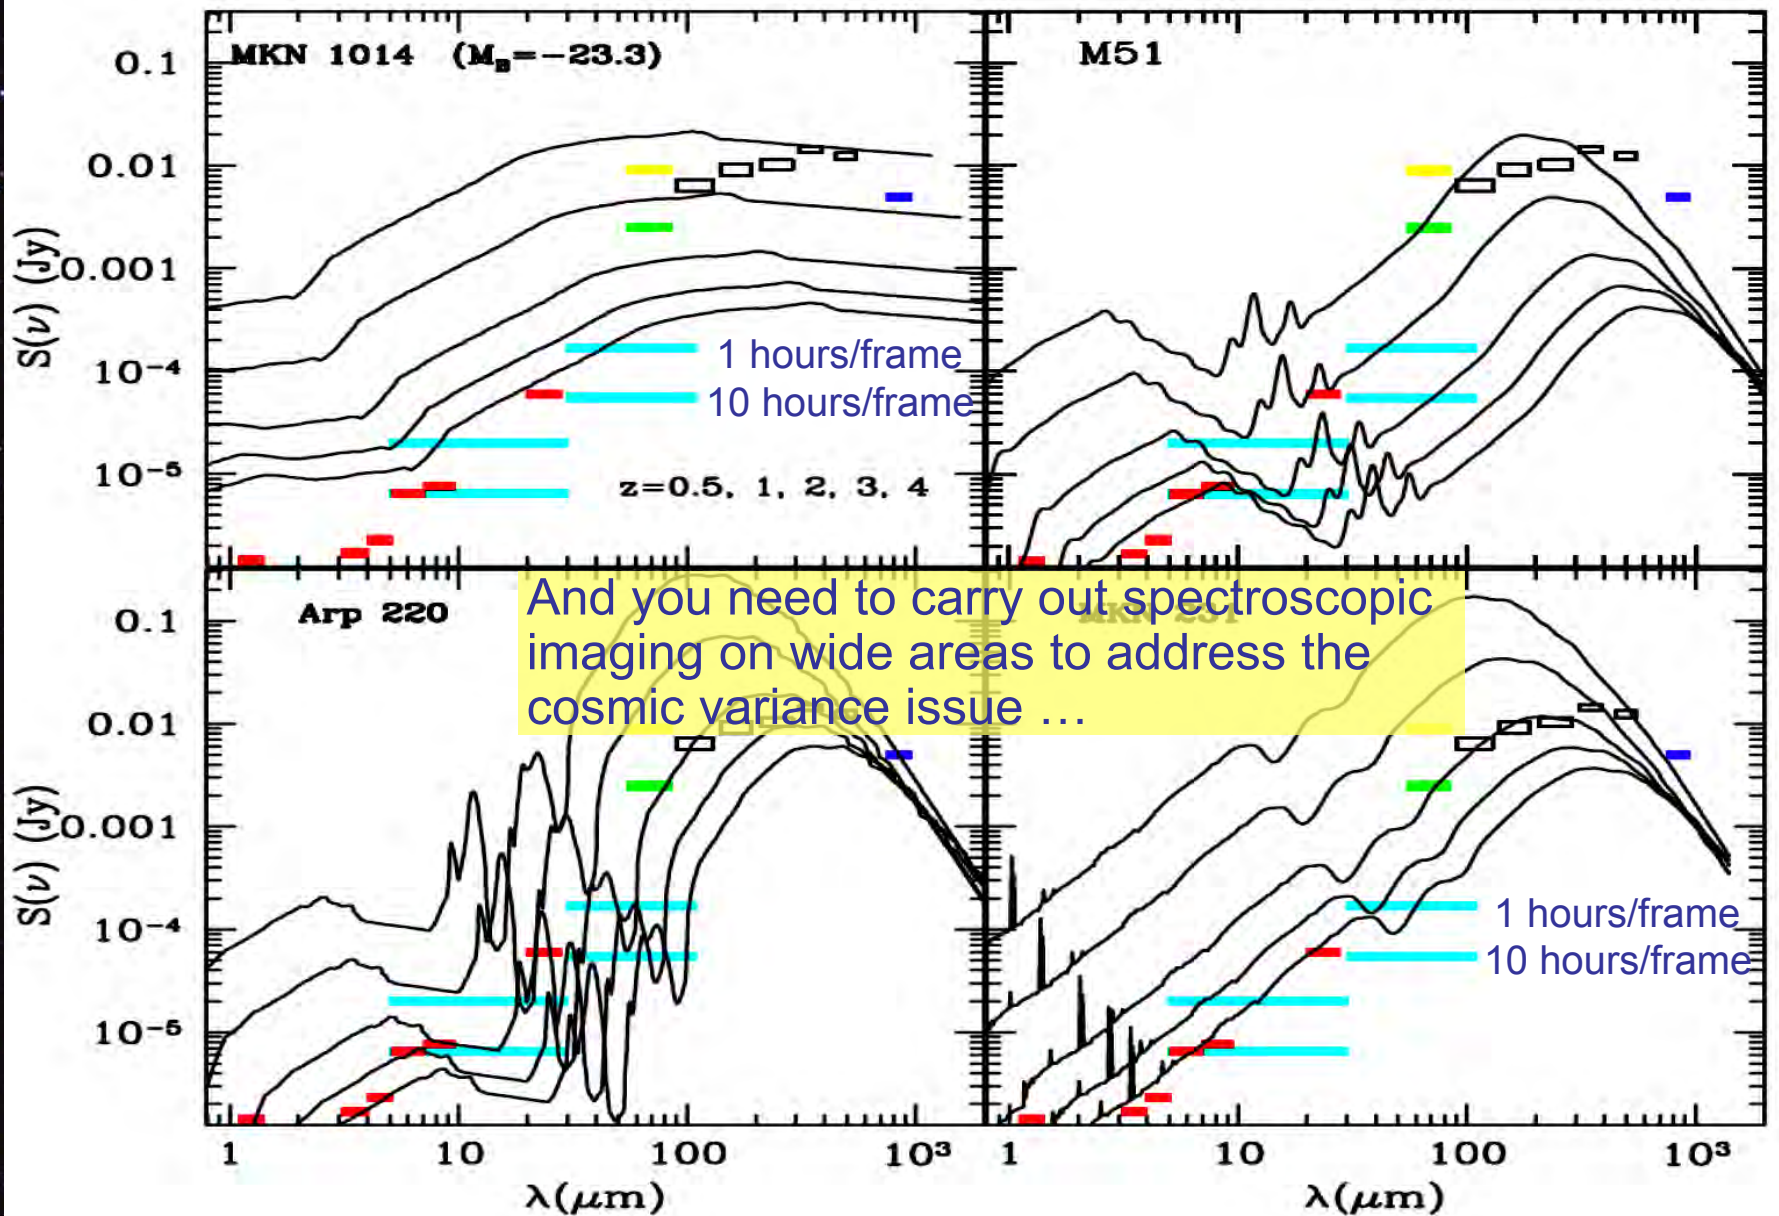

SAFARI low-res spectroscopic imaging mode

SPICA will have the sensitivity in low-resolution mode ($R \sim 100$) to detect PAH/silicate features in dusty distant galaxies out to $z \sim 3$ in 1 hour's integration, and out to $z > 4$ in 10 hours

SPICA low-res spec-imaging sensitivity

Summary

- ★ SPICA definitely appears as a perfect complement to planned instrumentation (JWST, ALMA) for cosmological investigations
- ★ Given the extraordinary sensitivity offered by the cooled instrumentation, SPICA/SAFARI might be the first tool for systematic investigation of the physics of high-redshift dusty cosmic sources through line studies (no extinction)
- ★ Deep multi-wavelength surveys and low-res spectroscopic imaging expected to open a new window for the discovery of sources over wide z -interval and their physical characterization
- ★ All this expected to be essential for uncharting the most elusive phases in the build-up of cosmic structure and the inter-relation of stellar formation and AGN accretion
